Abstract

In a commercial kitchen, a large ventilation rate is needed and energy consumption can be large because a large amount of effluence of heat and moisture need to be removed. To improve kitchen environment and to save the energy, low radiative cooking equipment with concentrated exhaust chimney was developed. Although a ventilation rate may be decreased by using this equipment, the effluence needs to be captured well. To predict indoor air and thermal environment of commercial kitchen using this equipment, CFD analysis is useful. In the previous study, the capture efficiency of the hood was measured when this new equipment is used. In this paper, CFD simulation was carried out in order to analyze capture efficiency of the equipment with reproducing the measurement. CFD results of various conditions were compared with measured ones. CFD results were agreed well with measured ones for many cases.

Keywords: Commercial Kitchen Ventilation, CFD Analysis, Capture Efficiency, Combustion Gas, Cooking Effluence

Introduction

In commercial kitchen, a large amount of heat and moisture are generated and they must be removed. Since the gas cooking equipment involves combustion, a kitchen in which gas
cooking equipment is used requires sufficient supply of oxygen for the combustion process. Hence, a large ventilation rate is required to meet the combustion and ventilation requirements resulting in high energy consumption.

A performance of the exhaust hood is important to remove contaminant and keep good air quality. The capture efficiency of hood has been examined previously under various room conditions. For example, Wolbrink and Sarnosky [1] defined capture efficiency as the ratio of moisture captured by the hood to moisture produced by the source. Li et al.[2] proposed new definition of capture efficiency which includes the air exchange between the cooking zone and the room zone in a two-zone mixing model. The capture efficiency of the standard canopy hood for exhaust gas and contaminant generated by cooking above the commercial cooking stoves and fryers were measured on two kinds of heat sources of natural gas and electromagnetic heat by Yamanaka et al.[3]. In addition, Momose et al. [4] investigated the influence of a moving person on the capture efficiency.

Recently, low radiative cooking equipment with concentrated exhaust chimney has been developed to improve the kitchen environment and conserve the HVAC energy requirements. A cross-section of the low radiative equipment is shown in Fig.1. The low radiative equipment has two advantages. Firstly, the surface temperature of the equipment is lower than that of the conventional equipment. This reduces radiation heat emission toward workers
and room surface. Secondly, generated combustion gas is exhausted effectively by using concentrated exhaust chimney. This reduces the diffusion and overflow of effluences to the room, which also contains the heat and CO2 waste gas from combustion. Consequently, the required exhaust flow rate can be reduced by these advantages. Although a ventilation rate may be decreased by using this equipment, there is no design guideline of ventilation system under operation of this type of equipment. Therefore the purpose of this study is to prove the ventilation performance of these equipments, and build up a design guideline of ventilation system under operation of them. To predict indoor air and thermal environment of commercial kitchen using this equipment, Computational Fluid Dynamics (CFD) analysis is useful. Authors [5] carried out CFD analysis on capture efficiency of the canopy hood for combustion gas and cooking effluence under operation of one kind of equipment operating in a laboratory. However, the simulation accuracy of exhaust plume was not so high suspect. Authors [6] also carried out simplified CFD analysis on indoor thermal environment under operation of three kinds of equipment operating in a room. However, this analysis disagrees with experimental result [5] due to the error in the boundary conditions. In this paper, first we carried out CFD analysis on capture efficiency of the canopy hood under operation of one kind of equipment in a large laboratory. We used measured data of exhaust air [7] and temperature [8] as boundary conditions of the analysis. Comparing with experimental result [5], simulation accuracy is checked. Secondly applying these boundary conditions, we carried
out CFD analysis on indoor thermal environment under operation of three kinds of equipment operating in a room which has supply and exhaust air like a real kitchen.

1. CFD Analysis on Capture Efficiency of the Hood in Large Space

1.1 Outline

CFD simulation was carried out in order to analyze the capture efficiency of the hood for combustion gas and cooking effluence under operation of one kind of the low radiative equipment in a laboratory. The laboratory measurements were carried out by Authors [5].

CFD outline is shown in Table 1.

1.2 Methods

As an analyzed room, experiment room of the study is simulated. The experimental space is in large of experimental building and the leakage from the hood is exhausted at ceiling height around the hood and it doesn’t capture again. Analyzed room is shown in Fig.2-Fig.3. The applications used for this analysis were low radiative range, fryer and kettle. A calculated domain is 4600*4200*3000mm space including a 1200*1200*500mm (2400*1200*500 in the case of kettle) canopy-type exhaust hood in the center. The height of the bottom of the hood is 2000mm. This is common used in the real kitchen. Each application is set under the center of hood. Initial Setting of indoor air temperature is 20 deg.C.
The standard k-\(\varepsilon\) model (SKE) and RNG k-\(\varepsilon\) model (RNG) are used as turbulence model. In order to exhaust contaminant from cooking equipment, the hood has an exhaust opening (300*300mm) at the center in the case of range and fryer, and it has two of them in the case of kettle. Assuming that the leakage from the hood is exhausted at ceiling height around the hood, the pressure at ceiling height is fixed as 0 Pa. The air is supplied from the lower part of surroundings walls (from floor to height 800mm). Supply air flow rate is 2 times of exhaust flow rate from exhaust opening at hood. As for the wall boundary condition, the generalized log law was applied for the velocity and adiabatic for thermal condition. Boundary conditions of the room are shown in Table 2. This CFD analysis was carried out under five conditions of exhaust flow rate, that is 20KQ (Case1), 30KQ (Case2), 40KQ (Case3), 0.3m/s of the face velocity at the bottom of the hood (Case4) and 0.4m/s of the face velocity (Case5) for each item of equipment. This method conforms to BL method [9] and is authorized as standard measuring method to determine the capture efficiency of a hood in JAPAN. Where, K is the Theoretical combustion gas flow rate per input [m\(^3\)/h \(\cdot\) KW] and Q is the gas input[KW]. These conditions are the same as the previous experiment. The analyzed exhaust and supply flow rate are shown in Table 3.

1.3 Boundary Conditions of the Equipments
The equipment models are shown in Fig.4. Boundary conditions of temperatures of cooking equipment surface, water vapor from the cooking pot and exhaust air from the exhaust opening were applied to the analysis. Since the radiative heat is very small compared to other heat transfer, it is not considered in this analysis. Air flow rate and temperature of combustion gas and ambient air to cool the equipment is based on the measurements. Latent heat of vaporization is calculated based on measured amount of vapor generation rate from the water per hour. Temperatures of cooking equipment surface were based on measured data. These boundary conditions of the equipment were shown in Table 4-Table 6.

2. CFD Analysis on Indoor Thermal Environment

2.1 Outline

CFD simulation was carried out in order to analyze indoor thermal environment of the room that three kinds of the low radiative cooking equipments with concentrated exhaust chimney are operated. The laboratory measurements were carried out by Authors [10]. By comparing CFD to Experiment, we validate the accuracy of CFD simulation. CFD outline is shown in Table 7.

2.2 Method
As an analyzed room, experimental room of the previous study is simulated. A plan, cross-section and perspective drawing of the analyzed room are shown in Fig.5. In the room of 4500*3500*2500mm, a low radiative kettle, range and fryer are installed from the left.

Boundary conditions of the each equipment are the same as chapter 1 (see Table 4-Table 6). The air is supplied from the three ceiling inlets and exhausted from three exhaust openings (350*350mm) of the hood (900*3500mm).

SKE is used as turbulence model. As for the wall boundary condition, the generalized log law was applied for the velocity and surface temperatures were based on measured data [10]. Simulation conditions of the equipment are shown in Table 4-Table 6. This CFD analysis was carried out under five conditions of exhaust flow rate, that is 20KQ (Case1), 30KQ (Case2), 40KQ (Case3) and 0.3m/s of the face velocity at the bottom of the hood (Case4) which is same as the experiment of the previous study TAKANO el at. [10]. The analyzed exhaust and supply flow rate are shown in Table 8.

3. Result and Discussion

3.1 Capture Efficiency of the Hood in Large Space

The capture efficiency $\eta$ is calculated as follows.

$$\eta = \frac{Q_n}{Q_n + Q_c}$$  \hspace{1cm} (Eq.1)

Where
\( Q_H \): Contaminant flow rate exhausted through the hood [kg/s]

\( Q_c \): Contaminant flow rate exhausted at ceiling height around the hood [kg/s]

In order to obtain capture efficiency, passive contaminants are released from a cooking pot as cooking effluence and from exhaust opening of the equipments as combustion gas. The capture efficiency obtained from CFD analysis and experimental is shown in Fig.6. With regard to CFD analysis result of both SKE and RNG, the capture efficiency of combustion gas (\( \eta_{\text{gas}} \)) and cooking effluence (\( \eta_{\text{cook}} \)) in the cases over Case4 of all equipments is 100%. This agrees with the experiment result. In addition, both \( \eta_{\text{gas}} \) and \( \eta_{\text{cook}} \) of RNG are higher than that of SKE. This is because that as to SKE, an updraft from the pot tends to spread water-vapor into the air. As for \( \eta_{\text{cook}} \) of Kettle for Case1-Case3, RNG agrees with the experimental result very well. As for \( \eta_{\text{gas}} \) of Kettle for Case1-Case3, however, both SKE and RNG are lower than experimental result. In comparison with SKE, RNG is close to experimental result. In general, SKE overestimates turbulence kinematic energy \( k \) around impinging stream [11]. In this simulation of the kettle, SKE overestimates turbulence kinematic energy \( k \) around a top panel of the hood. As for \( \eta_{\text{gas}} \) and \( \eta_{\text{cook}} \) of range for Case1-Case3, SKE and RNG are slightly higher than experimental result, but these can follow the experimental tendency. Flow rate exhausted from exhaust chimney opening may be overestimated. As for \( \eta_{\text{gas}} \) and \( \eta_{\text{cook}} \) of fryer for Case1-Case3, SKE agrees with the experimental result very well and RNG is slightly higher than experimental result. However,
experimental result are not so accurate between Case3 (311m3/h) and Case4 (1512m3/h).

This is because that experimental result has no data between them and it is largely-spaced (see Fig.6). Further measurements will be needed in the future. If it is assumed that measured data is higher than linearly-interpolated line between them, RNG may agree with experimental result.

In conclusion, some disagreements were seen due to the error in the boundary conditions or the turbulence model, but capture efficiency by CFD were agreed well with measured results for many cases. Thus, it seems that CFD model for each equipment in this section is faithful.

3.2 Indoor thermal environment

The vertical distributions of temperature in A-A’, B-B’ and C-C’ section (see Fig.5) of CFD simulation and measure data [10] are shown in Fig.7. As for all exhaust flow rates, the larger exhaust rate is, the lower indoor air temperature is and the smaller air temperature difference between the top and the bottom of the room is. These agree with the experimental result very well. This is because that the amount of heat removed from the room by the hood depends on exhaust rate. Especially, as to low exhaust flow rate, room air temperature of upper area is high due to a lot of heat leakage from the hood. This indicates that we can estimate indoor thermal environment in the room accurately. To estimate them accurately, we can use section the data of 3.1 (see Table 4-Table 6) for boundary conditions of these equipments.
Experimental measurement point of temperature is shown in Fig.8 and correlation charts between CFD temperature and experiment temperature are shown in Fig.9. As for most points, error is from -2deg.C to +2deg.C, and CFD is broadly consistent with experiment. As for some points of low temperature zone, temperature of CFD is lower than that of experiment. These points are close to the equipments. A minor change in the air movement may have significant effect upon the temperature, so the future researches are needed. Fig.10 shows the vertical temperature distribution of the room that is the average of the measurement points with the same height. CFD is consistent with experiment well. Although, as to the lower area, temperature of CFD is a slightly lower than that of experiment, this is the same tendency as shown in Fig.9.

Conclusions

In this paper, two CFD simulations are carried in order to estimate capture efficiency of the hood and indoor thermal environment in the room operated the low radiative cooking equipments with concentrated exhaust chimney. By comparing the CFD result with the past experimental result, the paper indicates that the CFD conditions of the equipment in this paper are faithful, and we can estimate indoor thermal environment accurately in the room operated the low radiative cooking equipments with concentrated exhaust chimney by using them.
